Abstract

This paper is devoted to the derivation and the analysis of vibrations of shallow spherical shell subjected to large amplitude transverse displacement. The analog for thin shallow shells of von Kármán’s theory for large deflection of plates is used. The validity range of the approximations is assessed by comparing the analytical modal analysis with a numerical solution. The specific case of a free edge is considered. The governing partial differential equations are expanded onto the natural modes of vibration of the shell. The problem is replaced by an infinite set of coupled second-order differential equations with quadratic and cubic non-linear terms. Analytical expressions of the non-linear coefficients are derived and a number of them are found to vanish, as a consequence of the symmetry of revolution of the structure. Then, for all the possible internal resonances, a number of rules are deduced, thus predicting the activation of the energy exchanges between the involved modes. Finally, a specific mode coupling due to a 1:1:2 internal resonance between two companion modes and an axisymmetric mode is studied.

Keywords: Shallow spherical shells; Geometrical non-linearities; Internal resonances, Non-linear vibrations

1. Introduction

Structures with a thin geometry, like beams, arches, plates and shells, can exhibit large amplitude flexural vibrations, whose magnitude is comparable to the order of their thickness. In those cases, typical non-linear
behaviors can be observed, such as jump phenomena and energy exchanges between modal configurations and a linear prediction model is not sufficient (Nayfeh and Mook, 1979). In this paper, von Kármán non-linear dynamic equations are used in the special case of a shallow spherical cap in order to predict and simulate the observed phenomena.

In the literature devoted to geometrically non-linear (finite-amplitude) vibrations of shells, the largest part of the studies is concerned with circular cylindrical shells. The interested reader can refer to the exhaustive review proposed by (Amabili et al., 1998). For the case of spherical caps, most of the studies including geometrical non-linearities deal with axisymmetric deflections of perfectly symmetric structures. Moreover, the focus is generally put on dynamic buckling and snap-through behavior, whereas vibratory responses are seldom treated. Some works dealing with non-linear vibration of shells are briefly reviewed here and the interested reader can refer for a thorough bibliography to reviews of the literature by Leissa (1993b), Qatu (2002), Moussaoui and Benamar (2002) as well as the recent paper by Amabili and Païdoussis (2003). Evensen and Evan-Iwanowsky (1967) proposed a very complete work, analytical and experimental, and investigate buckling as well as non-linear vibrations of a clamped-edge spherical cap with the harmonic balance method. Gonçalves (1994) addressed the same problem, with geometrical imperfections, and used a Galerkin method with the analytical expressions of the mode shapes to solve the problem. Ye (1997) used a numerical Runge–Kutta method to solve the same problem. However, those studies are restricted to vibrations involving only one axisymmetric mode. A detailed study is proposed by Yasuda and Kushida (1984) who investigated the multi-mode axisymmetric response of a clamped spherical cap. The special case of a 1:2 internal resonance between two axisymmetric modes was addressed both theoretically and experimentally. Grossman et al. (1969) investigated the free oscillations axisymmetric frequencies dependence with the deflection amplitude, as a function of both the curvature of the shell and the boundary conditions. All those studies are restricted to axisymmetric vibrations. However, even if the excitation pattern is rotationally symmetric, a complete realistic study has to include asymmetric vibrations, since non-linear coupling between any modal configuration is likely to appear. Hui (1983) addressed one-mode asymmetric vibrations of a complete spherical shell with geometric imperfections and structural damping. To the knowledge of the authors, no analytical studies on non-linear multi-mode asymmetric vibrations of spherical shells have been published and the present work aims at filling this gap.

Spherical caps can be considered as a reference problem, mainly because their vibrations display important non-linear behaviors that are commonly observed in large deflection vibrations of thin structures. Firstly, as a consequence of the multiplicity of two of eigenfrequencies associated to asymmetric modes—a common feature of structures with an axisymmetric geometry (see e.g. Morand and Ohayon, 1995, Chapter 1)—1:1 internal resonances between companion modes are numerous and give rise to a variety of complex vibratory patterns, including traveling waves (see e.g. Tobias and Arnold, 1957; Raman and Mote, 2001; Touzé et al., 2002). Secondly, the curvature of the structure adds quadratic non-linearities in the oscillators that govern the dynamics of the system, whereas only cubic terms are present in the case of transversely symmetric structures such as rods and plates (Thomas et al., 2001). Thirdly, the spectral content of spherical shells depends on one geometrical parameter related to the curvature. Particular algebraic relations between natural frequencies can then be obtained for specific values of the curvature. As a consequence, numerous internal resonances that are related to both quadratic and cubic non-linear terms are likely to be observed on spherical shells. An example addressed in the present work is the 1:1:2 internal resonance between an axisymmetric mode and two companion modes.

The main goal of this paper is to present an exhaustive method for analysis and prediction of the large amplitude vibratory response of spherical shells, from the governing equations to their resolution. It extends a study on non-linear vibrations of circular plates (Touzé et al., 2002) to the case a curved shallow geometry. The non-linear behavior and the possible energy transfers between modal configurations related to the perfect axisymmetric geometry of the structure are especially addressed, extending results of the
literature. The free-edge boundary conditions have been chosen mainly because they are the easiest to realize experimentally. However, the results of the present study can be extended to any type of boundary conditions, provided they are in accordance with the rotational symmetry of the problem.

The non-linear partial differential equations (PDE) that govern the oscillations of the shell are expanded onto its eigenmodes. The main underlying assumptions of the model, as well as the hypothesis of shallowness, are discussed. Complete analytical expressions of the eigenmodes of the associated linear problem are derived and compared to a numerical solution. After expansion of the PDE onto the eigenmodes, a set of coupled second-order ordinary differential equations with quadratic and cubic nonlinearities is obtained. The coefficients of the non-linear terms are calculated in the case of a perfect axisymmetric geometry and the coupling rules for the modal interactions are deduced. Possible truncation of the infinite dimensional problem are evaluated. Finally, the particular case of a 1:1:2 internal resonance is precisely investigated by a perturbation method, in the case of a harmonic forced excitation. The effect of slight imperfections of the structure is simulated by introducing slight differences in the companion modes frequencies. Experimental validations of the theoretical results will be presented in a forthcoming paper.

2. Formulation of the problem

2.1. Local equations

A spherical shell of thickness \( h \), radius of curvature \( R \) and outer diameter \( 2\alpha \), made of a homogeneous isotropic material of density \( \rho \), Poisson’s ratio \( v \) and Young’s modulus \( E \), is considered. The geometry is specified in Fig. 1.

The equations of motions for shallow shells subjected to large deflections and moderate rotations, with small strain so that Hooke’s law is verified, were derived by various authors in the case of particular geometries: Donnell (1934) and Evensen and Fulton (1965) for cylinders, Marguerre (1938), Leissa and Kadi (1971) and Alhazza (2002) for curved panels, Mushtari and Galimov (1961) and Koiter (1965) in the general case. A recent work presents a justification of these equations by an asymptotic method (Hamdouni and Millet, 2003). These equations have taken several names in the past: Donnell’s equations, Marguerre’s...
equations, Koiter’s equations or von Kármán’s equations. They correspond to a generalization to the case of a curved geometry of von Kármán’s model for large-deflection vibrations of plates (see e.g. Chu and Herrmann, 1956).

The main hypotheses are the following (see e.g. Koiter, 1965; Soedel, 1981):

- the shell is thin: \( h/a \ll 1 \) and \( h/R \ll 1 \);
- the shell is shallow: \( a/R \ll 1 \);
- the transverse normal stress are neglected with respect to the other stresses;
- Kirchhoff–Love hypotheses are used: the shear-strains are neglected and the normals to the undeformed mid-surface remain straight and normal and suffer no extension during the deformation;
- rotations of normals to the mid-surface are moderate, so that their sine and cosine are linearized (moderate rotations hypothesis);
- only the non-linear terms of the lowest order are kept in the strain expressions;
- the material is linear elastic, homogeneous and isotropic;
- in-plane and rotatory inertia are neglected;
- there is no membrane external forcing, which enables the use of an Airy stress function \( \Phi \).

With these assumptions fulfilled, one obtains the equations of motion in terms of the transverse displacement \( w \) along the normal to the mid-surface and the Airy stress function \( \Phi \), for all time \( t \)

\[
D \Delta w + \frac{1}{R} \Delta F + \rho \dot{w} = L(w, F) - c\dot{w} + p, \tag{1a}
\]

\[
\Delta F - \frac{Eh}{R} \Delta w = - \frac{Eh}{2} L(w, w), \tag{1b}
\]

where \( D = Eh^3/12(1 - v^2) \) is the flexural rigidity, \( c \) is a damping coefficient, \( p \) represents the external normal pressure, \( \dot{w} \) is the second partial derivative of \( w \) with respect to time, \( \Delta \) is the Laplacian and \( L \) is a bilinear quadratic operator. With the assumption that the shell is shallow, angle \( \varphi \) defined in Fig. 1 is small and we get

\[
\sin \varphi \simeq \varphi, \quad r = R \sin \varphi \simeq R\varphi. \tag{2}
\]

Hence, the position of any point of the middle surface of the shell can be measured by its polar coordinates \((r, \theta)\), \( r \in [0; a] \) and \( \theta \in [0; 2\pi] \) and the operators \( \Delta \) and \( L \) of Eqs. (1a) and (1b) can be written

\[
\Delta(\cdot) = (\cdot)_{,rr} + \frac{1}{r}(\cdot)_{,r} + \frac{1}{r^2}(\cdot)_{,\theta\theta}
\]

(3)

and

\[
L(w, F) = w_{,rr} \left( \frac{F_{,r}}{r} + \frac{F_{,\theta\theta}}{r^2} \right) + F_{,rr} \left( \frac{w_{,r}}{r} + \frac{w_{,\theta\theta}}{r^2} \right) - 2 \left( \frac{w_{,r\theta}}{r} - \frac{w_{,r}}{r^2} \right) \left( \frac{F_{,r\theta}}{r} - \frac{F_{,\theta}}{r^2} \right), \tag{4}
\]

where \( \cdot_{,\alpha\beta} = \partial^2(\cdot)/\partial \alpha \partial \beta \). Expressions of \( F \) as a function of membrane stresses can be found in Touze et al. (2002). Quadratic operator \( L \) defined by Eq. (4) has the same expression as in von Kármán’s equations for circular plates (Efstathiades, 1971). A proof of Eqs. (1a) and (1b) can be obtained after writing the doubly curved panel equations formulated in Leissa and Kadi (1971) in polar coordinates.

The shallowness assumptions of Eq. (2) are valid as long as \( \sin \varphi_0 \approx \varphi_0 \) (\( \varphi_0 \) is defined on Fig. 1). The corresponding shell geometries and limiting values of \( \varphi_0 \) are summarized in Fig. 2.
2.2. Free-edge boundary conditions

Boundary conditions are similar to those of a free-edge circular plate (Touzé et al., 2002) which yields for all \( t \) and \( h \), \( F \) and \( w \) are bounded at \( r = 0; \theta \),

\[
F_r + \frac{1}{a} F_{r\theta} = 0, \quad F_{r\theta} - \frac{1}{a} F_{,\theta} = 0, \quad \text{at } r = a, \quad (5a)
\]

\[
w_{rr} + \frac{v}{a} w_r + \frac{v}{a^2} w_{r\theta} = 0, \quad \text{at } r = a, \quad (5b)
\]

\[
w_{rrr} + \frac{1}{a} w_{rr} - \frac{1}{a^2} w_r - \frac{2 - v}{a^2} w_{r\theta} - \frac{3 - v}{a^3} w_{.,\theta} = 0, \quad \text{at } r = a. \quad (5c)
\]

The above equations stems from the vanishing of the external load at the edge: Eqs. (5b) are related to the membrane forces, Eq. (5c) to the bending moment and Eq. (5d) to the twisting moment and transverse shear force.

2.3. Dimensional analysis

Equations of motion (1a) and (1b) group different terms. On the one hand, terms \( \Delta F \) in Eq. (1a) and \( \Delta w \) in Eq. (1b) are responsible for a linear coupling between transverse motion and membrane stretching, stemming from the curved geometry of the shell. On the other hand, terms \( L(\cdot,\cdot) \) in both equations produce a non-linear coupling. Those two effects are independent from each other, since operator \( L \) is independent of curvature \( R \). If \( R \) tends to infinity, one obtains von Kármán’s equations (Efstathiades, 1971) for geometrically non-linear plates and if \( L(\cdot,\cdot) \) vanishes, linear Donnell–Mushtari–Vlasov’s model (Soedel, 1981) for shallow shells is obtained.

As the longitudinal inertia is neglected, \( F \) is slaved to transverse displacement \( w \). Eq. (1b) shows that \( F \) contains both a linear and a quadratic term in \( w \). By substituting \( F \) in Eq. (1a), one can show that curvature and non-linear coupling create together a linear, a quadratic and a cubic term in the equation that governs \( w \), the first two terms arising from curvature. In order to balance their magnitude, dimensionless quantities (denoted by overbars) are introduced

\[
w = w_0 \bar{w}, \quad F = F_0 \bar{F}, \quad r = a \bar{r}, \quad t = T_0 \bar{t}, \quad \text{with } T_0 = a^2 \sqrt{\frac{\rho h}{D}}. \quad (6)
\]

\( w_0 \) and \( F_0 \) will be specified next. Substituting these variables in Eqs. (1a) and (1b) and omitting for clarity damping and forcing terms, one obtains for Eq. (1a)
where \( \bar{\Delta w} = -\sigma \{ \bar{w} \} + \frac{1}{2} \varepsilon_{q} \{ \bar{w}^{2} \} - \varepsilon_{c} \{ \bar{w}^{3} \} \), \( \bar{w}^{n} \) denotes a dimensionless term proportional to \( \bar{w}^{n} \) supposed to be \( O(1) \). The order of magnitude of the different terms in Eq. (7) are specified by the following dimensionless factors:

\[
\begin{align*}
\text{linear term } \{ \bar{w} \} : \quad \chi &= \frac{Eh\alpha^{4}}{DR^{2}} = 12(1 - \nu^{2}) \frac{a^{4}}{R^{2}h^{2}}, \\
\text{quadratic term } \{ \bar{w}^{2} \} : \quad \varepsilon_{q} &= \frac{Eh\alpha^{2}}{DR} w_{0} = 12(1 - \nu^{2}) \frac{a^{2}}{Rh^{2}} w_{0}, \\
\text{cubic term } \{ \bar{w}^{3} \} : \quad \varepsilon_{c} &= \frac{Eh}{D} w_{0}^{2} = 12(1 - \nu^{2}) \frac{w_{0}^{2}}{h^{2}}.
\end{align*}
\]

From these developments it appears naturally that curvature adds a linear term, which depends on the geometry of the shell only (parameter \( \chi \)): it corresponds to the increase of transverse rigidity of the structure brought by the linear coupling between transverse motion and mid-plane stretching. It will be shown that \( \chi \) brings a correction to the shell eigenfrequencies compared to those of the corresponding plate (Section 3.1).

Non-linear terms have the order of magnitude of \( \varepsilon_{q} \) and \( \varepsilon_{c} \), which depends on the scaling \( w_{0} \) of transverse displacement. As

\[
\varepsilon_{c} = \frac{\varepsilon_{q}^{2}}{\chi},
\]

we find that cubic terms are of one order of magnitude smaller than that of quadratic terms. It is the usual scaling chosen for those terms when a perturbation method is used to solve the problem, so that these terms appear successively in the perturbative scheme (Nayfeh and Mook, 1979). We can also remark that the coefficient of cubic terms \( \varepsilon_{c} \) is independent of curvature \( R \) and that it is equal to the value it has in the case of a plate.

As a consequence, the balance between the magnitudes of the different terms is governed by the order of magnitude of transverse displacement \( w_{0} \) only. Table 1 summarizes values obtained for \( \varepsilon_{q} \) and \( \varepsilon_{c} \), for various choices of \( w_{0} \) as compared to \( h \). If the deflection is of the same order as the thickness (say \( w_{0} = h \)), \( \varepsilon_{q} \) and \( \varepsilon_{c} \) are greater than 1, no small parameter appears in Eq. (7) and non-linear terms are of a larger order than linear terms. If the deflection is chosen one order smaller than \( h \) (i.e. \( w_{0} = h/\alpha \)), cubic terms only are small compared to the linear ones. This is the usual scaling chosen in the case of plate (Sridhar et al., 1978; Touzé et al., 2002). When curvature is non-negligible, one has to choose deflection two orders smaller than

\( \chi, \varepsilon_{q} \) and \( \varepsilon_{c} \) are defined by Eqs. (8a)–(8c).
thickness \( w_0 = h^3/a^2 \) to obtain both quadratic and cubic terms smaller than the linear ones. This is the solution adopted here since a perturbation method will be used in Section 5 to solve Eqs. (1a) and (1b). The above developments about scaling of the deflection \( w_0 \) show that non-linear phenomena become significant in curved structures for deflections of an order of magnitude between \( h^3/a^2 \) and \( h^2/a \), smaller than in the case of plates.

The scaling \( F_0 \) of the stress function is chosen so that dimensionless variable \( F \) is \( O(1) \) when \( \Delta F \approx -1/2L(w,w) \) in Eq. (1b). This solution is suitable for any \( R \), especially if \( R \) tends to infinity (the case of a plate). The following dimensionless variables are then defined:

\[
  r = a\tilde{r}, \quad t = a^2\sqrt{\rho h/Dk}, \quad w = h^3/a^2\tilde{w}, \quad F = Eh^3/a^4\tilde{F},
\]

Substituting the above definitions in equations of motion (1a) and (1b) and dropping the overbars in the results, one obtains

\[
  \Delta\Delta w + \epsilon_q \Delta F + \ddot{w} = \epsilon_c L(w,F) + \epsilon_q [-2\mu\dot{w} + p],
\]

\[
  \Delta\Delta F - \frac{a^4}{Rh^3} \Delta w = -\frac{1}{2} L(w,w),
\]

where \( \epsilon_q = 12(1 - v^2)h/R \) and \( \epsilon_c = 12(1 - v^2)h^4/a^4 \). Boundary conditions (5a)–(5d), take the same form, with \( a = 1 \). Forcing and damping terms are scaled to the order of quadratic terms since only those nonlinear terms will be retained in the study of Section 5.

3. Modal analysis of the linear problem

3.1. Eigenfrequencies and mode shapes

An analytical expression of the natural frequencies of vibration of spherical shells with free-edge, axisymmetric as well as asymmetric, was proposed by Johnson and Reissner (1956). The main steps of the derivation of the expressions of the natural frequencies and mode shapes can be found in Appendix A and only some remarks are considered here. The eigenmodes of the problem are the solutions of

\[
  \Delta\Delta \Phi + \chi \Delta\Psi - \omega^2 \Phi = 0,
\]

\[
  \Delta\Delta\Psi = \Delta\Phi.
\]

They depend on one geometrical parameter only, the curvature parameter \( \chi \), that includes the joint influence of \( R, a \) and \( h \). Transverse and membrane mode shapes \( \Phi_{kn}(r,\theta) \) and \( \Psi_{kn}(r,\theta) \) have \( k \) nodal diameters and \( n \) nodal circles. Associated dimensionless angular frequencies \( \omega_{kn} \) are related to their dimensioned counterpart \( f_{kn} \) (in Hz) by the formula

\[
  f_{kn} = \frac{1}{2\pi a^2} \sqrt{\frac{E}{\rho h}} \omega_{kn} = \frac{h}{2\pi a^2} \sqrt{\frac{E}{12\rho(1 - v^2)}} \omega_{kn}.
\]

As membrane inertia is neglected, membrane motion is slaved to transverse motion. There are no membrane natural frequencies and each eigenfrequency \( \omega_{kn} \) is associated to \( \Phi_{kn}(r,\theta) \) and \( \Psi_{kn}(r,\theta) \) (Kalnin, 1964).
The modes with at least one nodal diameter \((k \geq 1)\) are called asymmetric modes. Each associated eigen-frequency has a multiplicity of two and the two corresponding independent modes are called companion or preferential configurations. The deformed shape of the first deduces from the other by a rotation of \(\pi/2k\) around the symmetry axis.

3.2. Dependence on curvature

Fig. 3 shows the evolutions of several eigenfrequencies \(\omega_{kn}\) with curvature parameter \(\chi\) and suggests to classify the modes in two families.

- The first family groups all asymmetric modes \((k, 0)\) with \(k\) nodal diameters \((k \geq 2\) since mode \((1, 0)\) is a solid-body mode) and no nodal circles. These modes can be called purely asymmetric, and their natural frequencies only slightly depend on the curvature (Fig. 3). Their deformed shape is shown in Fig. 4 and their dependence on \(\chi\) is shown on Fig. 5. Their transverse deformed shapes \(\Phi\) only slightly depend on the curvature and on the contrary, membrane deformed shapes \(\Psi\) show a significant dependence on curvature.

- The second family groups axisymmetric modes \((0, n)\) with \(n\) nodal circles and asymmetric modes with at least one nodal circle (thus called mixed modes), since their frequencies increase with curvature and are always sorted in the same order (Fig. 3). Their deformed shape is shown in Fig. 6. For \(k \in \{0, 1\}\) the deformed shape do not depends on curvature (see Eq. (A.14) in Appendix A). For \(k \geq 2\), the dependence is almost not visible (see Fig. 7), for both transverse and membrane modes.

![Fig. 3. Dimensionless natural frequencies \(\omega_{kn}\) of the shell as a function of curvature parameter \(\chi\). \((k, n)\) denotes the number of nodal diameters and circles, respectively.](image-url)
This analysis of the linear properties of the shell have importance even if one is interested in analyzing the non-linear vibratory regimes. The values of the natural frequencies governs the possible internal resonances relationships between modes and thus the possible modal interactions. This will be addressed in Section 4.2. The spatial dependence of the mode shapes are directly related to the values of the

Fig. 4. First three asymmetric mode shapes $\Phi_{kn}(r, \theta)$ with no nodal circles, classified in ascending order of their frequencies.

Fig. 5. Profiles of theoretical asymmetric (2,0) mode shape, for several values of $a/R$ between 0 and 0.6: (left) transverse mode and (right) membrane mode.

Fig. 6. First three axisymmetric and asymmetric mode shapes $\Phi_{kn}(r, \theta)$ with at least one nodal circle, classified in ascending order of their frequencies.
coefficients of the non-linear terms that governs the exchanges of energy between modes. This will be addressed in Sections 4.3 and 4.4.

3.3. Comparison with a numerical solution

In order to precise the validity range of the assumptions of shallowness of Eq. (2), theoretical results of Section 3.1 are compared to a numerical modal analysis, using the finite elements code CASTEM 2000 (Verpeaux et al., 1988) with DKT elements. Fig. 8 shows that the shallow theory predicts the natural frequencies with an error less than 1%, provided that $a/R < 0.3$. This result is in agreement with Table 2. A similar result has been established by Kalnins (1964) who compared the analytical natural frequencies stemming from (12a) and (12b) written in spherical coordinates—the so called non-shallow shell theory—to those of the shallow theory, derived by Johnson and Reissner (1956) and used in the present study.

Fig. 7. Profiles of theoretical axisymmetric $(0,1)$ and asymmetric $(1,1)$ and $(2,1)$ mode shapes, for $a/R \in [0,0.6]$ (left) transverse mode and (right) membrane mode.

Fig. 8. Ratio of analytical $\omega^\text{th}$ and numerical $\omega^\text{num}$ solutions for the eigenfrequencies of the shell, in percent, as a function of $a/R$. Geometry of the simulated shell is defined by $a = 300\text{mm}$ and $h = 1\text{mm}$ and several values of $R$. 
In order to study vibrations of shells with large curvature, it is possible to use in the following: (i) the eigenmodes calculated with a theoretical modal analysis in spherical coordinates (Kalnins, 1964), or (ii) to use numerical eigenmodes, calculated for example with the finite element method (see e.g. Lobitz et al., 1977, in the case of irregular plates). These tasks are beyond the scope of this article.

4. Modal expansion

4.1. Analytical expressions of the coupling coefficients

The aim of this section is to find a solution to the governing non-linear partial differential equations \((11a)\) and \((11b)\). The transverse deflection is expanded on the eigenmodes of the associated linear problem. The solution is sought as

\[
\begin{align*}
    w(r, h, t) &= \sum_{p} \Phi_{p}(r, h)q_{p}(t), \\
    F(r, h, t) &= F_{1} + F_{2} \quad \text{with} \quad \Delta F_{1} = \frac{a^{4}}{R^{2}h^{4}} \Delta w, \\
    \Delta F_{2} &= -\frac{1}{2} L(w, w).
\end{align*}
\]

The \(\{q_{p}\}_{p=1}^{\infty}\) are unknown functions of time—the modal coordinates—and \(\Phi_{p}\) is the \(p\)th mode shape of the shell with free edge, whose analytical expression is given in Appendix A.

First, Eq. \((11b)\) is solved by considering that

\[
\begin{align*}
    F &= F_{1} + F_{2} \quad \text{with} \quad \Delta F_{1} = \frac{a^{4}}{R^{2}h^{4}} \Delta w, \\
    \Delta F_{2} &= -\frac{1}{2} L(w, w).
\end{align*}
\]

Eq. \((15a)\) has already been solved for computing the linear modes in Section 3.1. Eq. \((15b)\) shows the same form as for a circular plate \((\chi = 0)\). It can be solved by using functions \(\Upsilon_{p}(r, 0)\) that exhibit the same spatial dependence as the transverse mode shapes of a clamped circular plate (Touze et al., 2002). Their expression, along with the values of zeros \(\zeta_{p}\), can be found in Appendix B. Finally, the stress function is written

\[
F(r, 0, t) = F_{1} + F_{2} = \frac{a^{4}}{R^{2}h^{4}} \sum_{b=1}^{\infty} \Psi_{b}(r, 0)q_{b}(t) + \sum_{b=1}^{\infty} \Upsilon_{b}(r, 0) \sum_{p=1}^{\infty} \sum_{q=1}^{\infty} G_{pq}q_{p}(t)q_{q}(t)
\]

### Table 2

Conditions on the number of nodal diameters and the expression in sine and cosine of the modes (both conditions must be fulfilled simultaneously) that lead to non-zero coefficients \(\beta_{pq}\) and \(\Gamma_{pq}\)

In order to study vibrations of shells with large curvature, it is possible to use in the following: (i) the eigenmodes calculated with a theoretical modal analysis in spherical coordinates (Kalnins, 1964), or (ii) to use numerical eigenmodes, calculated for example with the finite element method (see e.g. Lobitz et al., 1977, in the case of irregular plates). These tasks are beyond the scope of this article.
with
\[
G^b_{pq} = \frac{1}{2 \pi b} \iint_{\mathcal{S}_\perp} L(\Phi_p, \Phi_q) \mathcal{Y}_b dS \quad \text{and} \quad \iiint_{\mathcal{S}_\perp} \mathcal{Y}_b^2 dS = 1, \tag{17}
\]
where \( \mathcal{S}_\perp \) is the projected surface \( \mathcal{S} \) of the shell, i.e. the domain defined by \((r, \theta) \in [0, 1] \times [0, 2\pi] \).

This solution can now be substituted into (11a). Using Eq. (12a), multiplying by \( \Phi_s \), integrating over \( \mathcal{S}_\perp \) and using the orthogonality properties of the modes leads to, for all \( s \geq 1 \)
\[
\ddot{q}_s(t) + \omega_s^2 q_s(t) = \varepsilon_q \left[ -\sum_{p=1}^{+\infty} \sum_{q=1}^{+\infty} \beta^p_{pq} q_p(t) q_q(t) - 2\mu \ddot{q}_s(t) + \tilde{Q}_s(t) \right]
- \varepsilon_c \sum_{p=1}^{+\infty} \sum_{q=1}^{+\infty} \sum_{r=1}^{+\infty} \Gamma^s_{pqr} q_p(t) q_q(t) q_r(t), \tag{18}
\]
where modal damping \( \mu_s \), depending on mode \( \Phi_s \), has been considered. Expressions of \( \tilde{Q}_s(t) \), \( \beta^p_{pq} \) and \( \Gamma^s_{pqr} \) are
\[
\tilde{Q}_s(t) = \iiint_{\mathcal{S}_\perp} \Phi_s(r, \theta) p(r, \theta, t) dS, \tag{19}
\]
\[
\beta^p_{pq} = -\iiint_{\mathcal{S}_\perp} \Phi_s L(\Phi_p, \Phi_q) dS - \frac{1}{2} \sum_{b=1}^{+\infty} \frac{1}{\pi b} \iiint_{\mathcal{S}_\perp} \Phi_s L(\Phi_p, \Phi_q) \mathcal{Y}_b dS \iiint_{\mathcal{S}_\perp} \Phi_s \Delta \mathcal{Y}_b dS, \tag{20}
\]
\[
\Gamma^s_{pqr} = \frac{1}{2} \sum_{b=1}^{+\infty} \frac{1}{\pi b} \iiint_{\mathcal{S}_\perp} L(\Phi_p, \Phi_q) \mathcal{Y}_b dS \iiint_{\mathcal{S}_\perp} \Phi_s L(\Phi_u, \Phi_v) dS, \tag{21}
\]
with, for all \( p \geq 1 \)
\[
\iint_{\mathcal{S}_\perp} \Phi^2_p dS = 1. \tag{22}
\]

4.2. Reduced-order model

The initial problem described by the set of coupled partial differential equations (11a) and (11b) has been replaced by the equivalent discretized problem of the set (18) of non-linear coupled differential equations together with Eq. (14). At this stage, various approaches—analytical, numerical or a combination of both—can be used to solve the problem. In each cases, one has to truncate the set (18) to a finite number of oscillators. This operation has to be carefully performed, since too crude truncation lead to predict erroneous results for the trend of non-linearity (see e.g. Nayfeh et al., 1992; Amabili et al., 1999; Touzé et al., 2004). The non-linear normal modes and the normal form theory offers a theoretical framework that allows to properly truncate the set (18) (see e.g. Touzé et al., 2004; Touzé and Thomas, 2004). In particular, it is shown that all the non-linear modes involved in internal resonances must be retained in the analysis. In our problem with quadratic and cubic non-linear terms, internal resonances are defined by the possible following relations between the natural frequencies of the shell:

quadratic : \( \omega_p \simeq 2\omega_q \) or \( \omega_p \simeq \omega_q \pm \omega_k \), \( \tag{23a} \)

cubic : \( \omega_p \simeq 3\omega_q \) or \( \omega_p \simeq 2\omega_q \pm \omega_k \) or \( \omega_p \simeq \omega_q \pm \omega_k \pm \omega_m \). \( \tag{23b} \)
4.3. Coupling rules

For a perfect axisymmetric structure, mode shapes with \( k \) nodal diameter are written in terms of \( \cos k\theta \) and \( \sin k\theta \). As coefficients \( \beta_{pq}^\nu \) and \( \Gamma_{pq}^\nu \) involve integrations of products of those functions (see Eqs. (20) and (21)), a number of them vanish. The goal of the present section is to exhibit some rules that determine which coefficients vanish and consequently which modal interactions are possible. The mathematical derivations can be found in Appendix C.

Conditions for \( b_{sp} \) and \( C_{sp} \) to be non-zero are summarized in Table 2. They depend on (i) the number of nodal diameters \( k_s, k_p, k_q \) and \( k_u \) of the modes \( U_s, U_p, U_q \) and \( U_u \) involved in the calculation of \( b_{sp} \) and \( C_{sp} \) and (ii) the angular dependence in \( \cos k\theta \) or \( \sin k\theta \) of each of \( U_s, U_p, U_q \) and \( U_u \). The number \( n \) of nodal circles has no influence.

Among those coefficients, some of them are involved in resonant non-linear terms. Those terms are called resonant because they can be viewed as forcing terms that excite a particular mode close to its resonance, when internal resonances relations between the natural frequencies exist. They are thus responsible for strong coupling—and thus large energy exchanges—between modal configurations. They cannot be removed by the computation of the normal form and thus govern the dynamics of the system (Guckenheimer and Holmes, 1983). As some coefficients vanish, the corresponding resonant terms are canceled and certain energy exchanges are impossible, even if relations of the form of Eqs. (23a) and (23b) are fulfilled. The end of this section exhibits a few rules that enable to predict the possible modal interactions.

In order to determine if a particular modal interaction is possible, one has (i) to check if any of Eqs. (23a) and (23b) is fulfilled and (ii) to check if the associated resonant terms are non zero, using the following rules that hold on the number of nodal diameters of the involved modes. The rules holding on the nature in sine or cosine of companion modes are secondary because they cannot be responsible of cancellation of all resonant terms in a particular internal resonance. They are thus not addressed here.

The first rule stands that all axisymmetric modes can be involved in modal interactions with one another, by both order-two (Eq. (23a)) and order three (Eq. (23b)) internal resonances. Studies on modal interactions between axisymmetric modes were proposed by Sridhar et al. (1975) for circular plates and by Yasuda and Kushida (1984) in the case of spherical shells. The other rules, specifically related to particular internal resonances involving asymmetric modes, are given below. One should keep in mind that two asymmetric modes with natural frequencies such that \( \omega_2 > \omega_1 \) can have their numbers of nodal diameters such that \( k_2 < k_1 \); this situation exists if the numbers of nodal circles are such that \( n_2 > n_1 \) (see e.g. Fig. 3).

4.3.1. Order-two internal resonances

The coupling rules are summarized in Tables 3 and 4. Each table specifies the internal resonance considered (first line), the involved modes (second line), the resonant terms (third line) and the general conditions.

| Table 3 |
| Rules determining if modal interaction between modes \( \Phi_1 \) and \( \Phi_2 \) is possible, when internal resonance \( \omega_2 = 2\omega_1 \) is fulfilled |

on the numbers of nodal diameters that lead to non-zero resonant terms and thus to a possible energy exchange between the involved modes (fourth line). Then, the particular cases of involved axisymmetric modes and/or asymmetric modes are considered (remaining lines).

These order-two internal resonances are specific to shells with a non-zero curvature, since plates show only order-three internal resonances. Section 5 of this paper is related to the case of Table 3.

4.3.2. Order-three internal resonances

The coupling rules are summarized in Tables 5–7, in a similar manner as for the previous case of order-two internal resonances. Some cubic non-linear terms are always resonant, even if no cubic internal resonance (Eq. (23b)) is fulfilled. An example is a term \(q_i q_j^2\), which is resonant in the \(i\)th oscillator (of natural frequency \(\omega_i\)) for any value of the natural frequency \(\omega_j\) of mode \(\Phi_j\), since \(\omega_i = \omega_i + \omega_j - \omega_j\). It can be proved (Sridhar et al., 1975; Lacarbonara et al., 2003) that those terms do not lead to large energy exchanges if they are the only ones present in the equations. Thus, only resonant terms specifically related to the cubic internal resonances of Eq. (23b) are considered in Tables 5–7.

These order-three internal resonances are common to any shell; in particular, they are the only internal resonances involved in vibrations of plates (when \(\chi = 0\)). However, they are of significant importance for shells with small curvature only, since cubic non-linear terms become negligible with respect to quadratic terms for large curvatures (\(\epsilon_c \ll \epsilon_q\) if \(R\) is small compared to \(a\), see Table 1). The case of Table 5 has been recently addressed by Lee et al. (2003) and cases of Tables 6 and 7 extend earlier results of Sridhar et al., 1978), corrected by Yeo and Lee (2002), in the case of circular plates.

4.4. Influence of curvature

Some numerical values of coefficients are now exhibited to evaluate the dependence of coefficients $p_{pq}^k$ and $p_{pq}^k$ on the curvature of the shell. They were computed numerically using Eqs. (20) and (21) with the analytical expressions of the mode shapes of Appendix A and B.
Table 8 shows several values of quadratic coefficients $a_i$ of resonant terms in the case of the 1:1:2 internal resonance treated in Section 5 (The coefficients are defined by Eqs. (25a)–(25c)). Fig. 9 presents the evolution of the relative value of coefficients $a_i$, that is the ratio of $a_i$ to its value for $v = 10/C_0^9$. One can observe that these quadratic coefficients depend only slightly on the curvature parameter $v$. Moreover, the relative evolution with respect to $v$ of coefficient $a_1 = a_2$ is identical to that of $a_3 = a_4$, for a given value of the number $k$ of nodal diameters of the companion modes. This is a consequence of the fact that for a given value of $k$, the $\{a_i\}_{i=1,\ldots,4}$ all depend on the same modal shapes ($U_{k,0}$ and $U_{0,1}$).

Table 9 shows the only cubic coefficient that is involved in a single axisymmetric mode vibration. It does not depend on $v$. The same table and Fig. 10 shows coefficient of the 1:1 internal resonance between two companion purely asymmetric modes with $k$ nodal diameters (and no nodal circles). They depend very

![Fig. 9. Evolution of coefficients of quadratic resonant terms of Table 8 with respect to curvature parameter $\chi$, for $k \in \{2, \ldots, 7\}$: (—) ratio of $a_1 = a_2$ to their value for $\chi = 10^{-9}$ and (–) ratio of $a_3 = a_4$ to their value for $\chi = 10^{-9}$.](image-url)
slightly on the curvature parameter $v$. The numerical values of this latter case are in agreement with those computed in Touzé et al. (2002) for a circular plate.

One can conclude that coefficients are almost constant as a function of $v$. It is a consequence of the fact that the shell mode shapes slightly depend on curvature, as shown in Section 3.1. Thus, the dependence of the dynamics of the shell upon its geometry is mainly governed by the value of $e_q$ (Eq. (8b)), since $e_c$ is a constant with respect to the curvature (Eq. (8c)).

5. Application: the case of a one-to-one-to-two internal resonance

This section is devoted to the analysis of a system exhibiting a one-to-one-to-two (1:1:2) internal resonance, corresponding to the interaction between two companion asymmetric mode with an axisymmetric mode, whose natural frequency is nearly equal to twice that of the asymmetric ones. This specific internal
resonance is studied here because it has been observed on a real shell at the laboratory, with energy transfer between the first \((0,1)\) axisymmetric mode and the sixth \((6,0)\) asymmetric. Fig. 11 shows the vibration pattern measured with a scanning laser vibrometer, when the structure is excited at its center by means of a sinusoidal forcing. The vibrations patterns resulting from two excitation conditions—related to two frequencies of excitations close to the natural frequency of the \((0,1)\) mode—are shown on Fig. 11, with and without coupling with one of the companion asymmetric \((6,0)\) modes. Precise measurements and model fitting will be reported in a forthcoming paper.

Two-to-one internal resonance occurs in many different physical systems and has been already studied by a number of investigators (see e.g. Nayfeh and Balachandran, 1989; Nayfeh, 2000, and references therein, for a quick survey including references on spring pendulum, ships, surface waves in closed basins, etc.). For mechanical systems displaying geometrical non-linearities, this specific resonance has been studied both theoretically and experimentally for a structure composed of two slender beams and two dense masses, which were adjusted so that the first two natural frequencies were in the ratio 1:2 (Haddow et al., 1984; Nayfeh and Zavodney, 1988). The two-dof dynamical system has also been studied by Miles (1984), Yamamoto and Yasuda (1977), and the particular phenomenon of saturation was exhibited. As structures with curvature display quadratic non-linearity, 1:2 resonance has naturally been studied for the vibrations of arches and suspended cables (see e.g. Tien et al., 1994; Benedettini et al., 1995).

In the field of circular cylindrical shell vibrations, Nayfeh and Raouf (1987) performed a similar study, as they investigated the interaction between an axisymmetric mode and the two configurations of an asymmetric mode. However, they only considered the perfect case of an infinitely long cylinder. In particular they did not take into account the small detuning that necessary occur between the two preferential configurations in a real system. We will show that these imperfections have a fundamental role for explaining the experimentally observed coupling. More recently, they proposed a second-order solution (Chin and Nayfeh, 2001). Robie et al. (1999) also studied the 1:2 internal resonance, but they limited their study to free undamped vibrations, and considered one asymmetric configuration only. Alhazza (2002) analyzed the 1:2 resonance for a doubly-curved cross-ply shallow shell. Finally, a 1:1:1:2 resonance in circular cylindrical shells has been studied by Amabili et al., but the forcing was considered on one preferential configuration, thus naturally leading to coupled solutions with the first and third axisymmetric mode for any vibration amplitude (Amabili et al., 2000, Pellicano et al., 2000). Moreover, the two configurations were supposed to have exactly equal eigenfrequencies.

The present developments are aimed at filling the gap between the previous studies and shedding light on the relevance of the parameters that are specifically connected to the imperfection of the shell. More specifically, it will be shown that those parameters are crucial for understanding the nature of the coupled

Fig. 11. Vibration pattern with (right) and without (left) coupling between the \((0,1)\) mode and a purely asymmetric \((6,0)\) mode, measured on a real shell with a scanning laser vibrometer. The geometry of the shell is defined by \(a = 300\, \text{mm}, R = 1.515\, \text{m}\) and \(h = 1\, \text{mm}\).
regime. It will be demonstrated that the energy transfer is specific to one of the companion asymmetric modes and that no traveling wave appear as long as the cubic terms are effectively negligible.

The spherical shell is assumed to be excited by an external sinusoidal force located at its center, whose frequency \( \Omega \) is chosen close to the natural frequency (denoted here by \( \omega_3 \)) of an axisymmetric mode \((0,n')\) of \( n' \) nodal circles. The curvature parameter \( \chi \) is chosen so that an internal resonance exist between mode \((0,n')\) and two companion asymmetric modes \((k,n)\) of frequencies \( \omega_1 \) and \( \omega_2 \), so that \( \omega_3 \approx 2\omega_1 \approx 2\omega_2 \). Fig. 3 shows that these internal resonances occur for many values of \( \chi \). For example, mode \((0,1)\) can be involved in a 1:1:2 internal resonance between any of the asymmetric modes \((k,0)\) with no nodal circles. In the following, a reduced order model is deduced from the set (18) and we focus on a first-order perturbative solution. As a consequence, (i) only the modes involved in internal resonance are retained, (ii) the cubic terms are neglected with respect to the others, according to the values of the parameters \( \varepsilon_q \) and \( \varepsilon_t \) (see Table 1) and (iii) all non-resonant terms are dropped. The transverse displacement \( w(r,\theta,t) \) is then written

\[
w(r,\theta,t) = R_{kr}(r)(q_1(t)\cos k\theta + q_2(t)\sin k\theta) + R_{0r}q_3(t),
\]

where \( q_1 \) and \( q_2 \) are related to the asymmetric modes and \( q_3 \) to the axisymmetric. \( R_{kr}(r) \) and \( R_{0r}(r) \) are defined in Appendix A. The \( \{q_i\}_{i=1,...,3} \) are solutions of the following set, deduced from (18):

\[
\begin{align*}
\dot{q}_1 + \omega_1^2 q_1 &= \varepsilon_q [x_1 q_1 q_3 - 2\mu_1 \dot{q}_1], \\
\dot{q}_2 + \omega_2^2 q_2 &= \varepsilon_q [x_2 q_2 q_3 - 2\mu_2 \dot{q}_2], \\
\dot{q}_3 + \omega_3^2 q_3 &= \varepsilon_q [x_3 q_1^2 + x_4 q_2^2 - 2\mu_3 \dot{q}_3 + Q \cos \Omega t].
\end{align*}
\]

The forcing terms of the first two oscillators (25a) and (25b) vanish since the corresponding modes have a node at the center of the shell. The term proportional to \( q_3^2 \) in Eq. (25c) is not considered since it is non-resonant. The reduced-order model defined above is justified because the present study is focused on the loss of stability of the single degree-of-freedom (sdof) solution (defined by the directly excited axisymmetric mode only, \( q_3(t) \equiv q_3(t) \equiv 0 \)). A first-order perturbative development is then sufficient and the formalism of non-linear normal modes need not to be used (Nayfeh and Nayfeh, 1994). This would not be the case if one was interested in predicting the hardening or softening behavior of a single mode. In this situation, it would be necessary to retain a number of additional oscillators in the model, the cubic terms as well as the non-resonant terms, as shown for example in the case of circular cylindrical shells by Amabili et al. (1999) or in a general case by Touzé et al. (2004) with the formalism of non-linear modes.

Coefficients \( \{x_i\}_{i=1,...,4} \) can be computed from the \( \beta_{qr}^p \) expressed in Eq. (20). In a perfect case, one obtains \( x_1 = x_2 \), and \( x_3 = x_4 \), as shown in Table 8. However, for the sake of generality, the \( \{x_i\}_{i=1,...,4} \) are kept variable in the following. To express the internal resonance relationships, we introduce two internal detuning parameters \( \sigma_0 \) and \( \sigma_1 \):

\[
\begin{align*}
\omega_2 &= \omega_1 + \varepsilon_q \sigma_0, \\
\omega_3 &= 2\omega_1 + \varepsilon_q \sigma_1.
\end{align*}
\]

One can notice that: \( \omega_3 = 2\omega_2 + \varepsilon_q (\sigma_1 - 2\sigma_0) \). Finally an external detuning parameter \( \sigma_2 \) is introduced to express the nearness of the forcing frequency with the axisymmetric natural frequency

\[
\Omega = \omega_3 + \varepsilon_t \sigma_2.
\]

5.1. Multiple scale solution

System (25) is solved by the method of multiple scales. To the first-order, and for \( j = 1,2,3 \)

\[
q_j(t) = q_{j1}(T_0, T_1) + \varepsilon_q q_{j2}(T_0, T_1) + O(\varepsilon_q^2),
\]
where $T_0 = t$ and $T_1 = e^{qt}$. The first-order equations lead to express the $\{q_j\}_{j=1,2,3}$ as
\[
q_j(T_0, T_1) = \frac{1}{2} a_j(T_1) \exp(i \theta_j(T_1)) \exp(i \omega_j T_0) + \text{c.c.,}
\]
where c.c. stands for complex conjugate. Polar form is used to express the amplitude of the first-order solutions, which depends on the slow time scale $T_1$. Introducing (29) into the second-order equations leads to the so-called solvability condition, which can be written as a six-dimensional dynamical system by separating real and imaginary parts. Finally, the following variables allows definition of an autonomous dynamical system:
\[
\gamma_1 = \sigma_1 T_1 + \theta_1 - 2 \theta_1, \quad \gamma_2 = (\sigma_1 - 2\sigma_0) T_1 + \theta_3 - 2 \theta_2, \quad \gamma_3 = \sigma_2 T_1 - \theta_3.
\]
It reads
\[
da' = -\mu_1 a_1 + \frac{x_1 a_1 a_3}{4 \omega_1} \sin \gamma_1,
\]
\[
\gamma_1' = \sigma_1 - \frac{x_3 a_1^2}{4 \omega_3 a_3} \cos \gamma_1 - \frac{x_4 a_2^2}{4 \omega_3 a_3} \cos \gamma_2 - \frac{Q}{2 \omega_3 a_3} \cos \gamma_3 + \frac{x_3 a_3}{2 \omega_1} \cos \gamma_1,
\]
\[
da' = -\mu_2 a_2 + \frac{x_2 a_2 a_3}{4 \omega_2} \sin \gamma_2,
\]
\[
\gamma_2' = \sigma_1 - 2 \sigma_0 - \frac{x_3 a_1^2}{4 \omega_3 a_3} \cos \gamma_1 - \frac{x_4 a_2^2}{4 \omega_3 a_3} \cos \gamma_2 - \frac{Q}{2 \omega_3 a_3} \cos \gamma_3 + \frac{x_2 a_3}{2 \omega_2} \cos \gamma_2,
\]
\[
da' = -\mu_3 a_3 - \frac{x_3 a_1^2}{4 \omega_3} \sin \gamma_1 - \frac{x_4 a_2^2}{4 \omega_3} \sin \gamma_2 + \frac{Q}{2 \omega_3} \sin \gamma_3,
\]
\[
\gamma_3' = \sigma_2 + \frac{x_3 a_1^2}{4 \omega_3 a_3} \cos \gamma_1 + \frac{x_4 a_2^2}{4 \omega_3 a_3} \cos \gamma_2 + \frac{Q}{2 \omega_3 a_3} \cos \gamma_3,
\]
where $(\cdot)'$ stands for the derivation with respect to $T_1$.

5.2. Fixed points

Fixed points for Eq. (31) are obtained by cancelling the left-hand side terms, which involve a derivative with respect to time. There are a priori four kinds of fixed points:

(i) sdof solution. It corresponds to the case where $a_1 = a_2 = 0$: no energy transfer between modes occur and the response of the system is governed by the directly excited axisymmetric mode only. Its amplitude is given by
\[
a_3 = \frac{Q}{2 \omega_3 \sqrt{\sigma_3^2 + \mu_3^2}},
\]
(ii) C1 solution. It corresponds to a coupling between the axisymmetric mode and the first asymmetric configuration, thus $a_1 \neq 0$, and $a_2 = 0$.

(iii) C2 solution. The coupling is here with the second asymmetric configuration: $a_1 = 0$, and $a_2 \neq 0$.

(iv) C3 solution. Coupling with both asymmetric configurations at the same time, leading to $a_1 \neq 0$ and $a_2 \neq 0$. It will be shown next that this solution exists only in the perfect case.
Analytical expressions for the $C1$ and $C2$ solutions are easily available with a little algebra, which is not reproduced here (see e.g. Nayfeh and Raouf, 1987; Nayfeh and Mook, 1979; Haddow et al., 1984). One then obtains:

- **$C1$ solution:**

  \[
  a_3 = \frac{2\omega_1}{\bar{\alpha}_1} \sqrt{4\mu_1^2 + (\sigma_1 + \sigma_2)^2},
  \]
  \[
  a_1 = 2 \sqrt{-\Gamma_1 \pm \sqrt{\frac{Q}{4\bar{\alpha}_1^2} - \Gamma_1^2}},
  \]

  with:

  \[
  \Gamma_1 = \frac{2\omega_1\omega_3}{\bar{\alpha}_1\bar{x}_3} (2\mu_1\mu_1 - \sigma_2(\sigma_1 + \sigma_2)),
  \]

  and:

  \[
  \Gamma_2 = \frac{2\omega_1\omega_3}{\bar{\alpha}_1\bar{x}_3} (2\sigma_2\mu_1 + \mu_3(\sigma_1 + \sigma_2)).
  \]

- **$C2$ solution:**

  \[
  a_3 = \frac{2\omega_2}{\bar{\alpha}_2} \sqrt{4\mu_2^2 + (\sigma_1 - 2\sigma_0 + \sigma_2)^2},
  \]
  \[
  a_2 = 2 \sqrt{-\Gamma_3 \pm \sqrt{\frac{Q}{4\bar{\alpha}_2^2} - \Gamma_3^2}},
  \]

  with:

  \[
  \Gamma_3 = \frac{2\omega_2\omega_3}{\bar{\alpha}_2\bar{x}_4} (2\mu_2\mu_1 - \sigma_2(\sigma_1 - 2\sigma_0 + \sigma_2)),
  \]

  and:

  \[
  \Gamma_4 = \frac{2\omega_2\omega_3}{\bar{\alpha}_2\bar{x}_4} (2\sigma_2\mu_2 + \mu_3(\sigma_1 - 2\sigma_0 + \sigma_2)).
  \]

One can notice that the symmetry of the original equations (25) allows derivation of the expression for the $C2$ solution from the expression found for $C1$. The symmetry of the system is of great help for the understanding and analysis of energy transfer, as shown next.

The $C3$ case is considered by keeping all amplitudes different from zero. However, the operations that lead to Eqs. (33a) and (34a) are still possible. Thus, in the more general case, when the two asymmetric configurations are eventually present in the vibration, $a_3$ can take the two different values given by (33a) and (34a). Moreover it can be shown that if $a_3$ is equal to (33a) (respectively, equal to (34a)), then $\gamma_2$ (respectively, $\gamma_1$) is undefined and $a_2 = 0$ (respectively, $a_1 = 0$) is the only possible case. As a consequence, no other solutions than the ones already described (sdof, $C1$ and $C2$) are available, except when Eqs. (33a) and (34a) are simultaneously fulfilled, which is true only in the perfect case (defined by: $\mu_1 = \mu_2$, $\bar{\alpha}_1 = \bar{\alpha}_2$, and $\omega_1 = \omega_2$, which implies $\sigma_0 = 0$). The stability analysis confirms these conclusions, as well as numerical simulations which were conducted with the software DsTool (Guckenheimer et al., 1995).
5.3. Stability analysis

A linear stability analysis is performed by computing the Jacobian matrix $J$ of Eq. (31). We first investigate the stability of the sdof solution. The eigenvalues are

$$\lambda_{1,2}^{\text{sdof}} = -\mu \pm i\sigma,$$  \hspace{1cm} (35a)

$$\lambda_1^{C_1} = -\mu_1 + \frac{a_3}{4\omega_1} \sin \gamma_1,$$  \hspace{1cm} (35b)

$$\lambda_2^{C_1} = -\frac{a_3}{2\omega_1} \sin \gamma_1,$$  \hspace{1cm} (35c)

$$\lambda_1^{C_2} = -\mu_2 + \frac{a_3}{4\omega_2} \sin \gamma_2,$$  \hspace{1cm} (35d)

$$\lambda_2^{C_2} = -\frac{a_3}{2\omega_2} \sin \gamma_2.$$  \hspace{1cm} (35e)

The superscripts indicate that each pair of eigenvalues can be easily related to: (i) the stability of the sdof solution with respect to perturbations contained within the subspace $a_1 = a_2 = 0$ (sdof case), (ii) its stability with respect to perturbations caused by the presence of the first asymmetric configuration (C1 case), (iii) its stability with respect to perturbations caused by the second asymmetric configuration (C2 case). The simple form of Eq. (35a–e) is a direct consequence of the relative decoupling and symmetry of the initial equations (25). By forming the products $\lambda_1^{C_1} \lambda_2^{C_1}$ and $\lambda_1^{C_2} \lambda_2^{C_2}$, and eliminating $\gamma_1$ and $\gamma_2$ in favor of the other parameters, one can exhibit two stability conditions for the sdof solutions:

$$a_3 \leq L_1(\sigma_2), \quad \text{where} \quad L_1(\sigma_2) = 2\omega_1 \frac{\sqrt{4\mu_1^2 + (\sigma_1 + \sigma_2)^2}}{x_1},$$  \hspace{1cm} (36)

$$a_3 \leq L_2(\sigma_2), \quad \text{where} \quad L_2(\sigma_2) = 2\omega_2 \frac{\sqrt{4\mu_2^2 + (\sigma_1 - 2\sigma_0 + \sigma_2)^2}}{x_2},$$  \hspace{1cm} (37)

with $a_3$ defined by Eq. (32). These stability conditions have been reported in Fig. 12, where the sdof solutions is unstable in the gray shaded regions.

In the perfect case—i.e., defined by the complete identity of the two configurations (i.e. $x_1 = x_2$, $\omega_1 = \omega_2$ and $\mu_1 = \mu_2$), the two curves $L_1(\sigma_2)$ and $L_2(\sigma_2)$ are merged. Hence both configurations are simultaneously excited when the sdof curve crosses $L_1 \equiv L_2$. It can then be shown that their amplitudes verify the following relationship:

$$a_1^2 + a_2^2 = -4\Gamma_1 + \sqrt{16\Gamma_1^2 - \frac{64\omega_1^2 \omega_2^2}{x_1^2 x_3^2} (4\mu_1^2 + (\sigma_1 + \sigma_2)^2)(\mu_1^2 + \sigma_2)^2} - \frac{4Q^2}{x_3^2}.$$  \hspace{1cm} (38)

An infinity of coupled solutions are available: any solution that verify Eq. (38). This has been verified numerically. The reader interested in the perfect case is referred to Nayfeh and Raouf (1987) for a complete study.

In real situations, it is impossible to ensure perfectness, and slight perturbations are always present that break the precedent results and keep the curves $L_1(\sigma_2)$ and $L_2(\sigma_2)$ distinct, so that the situation depicted in Fig. 12 is generic. The discussion is restricted to positive values of $\sigma_0$, because the ordering of the configurations is made by their natural frequencies.

The stability of the C1 and C2 solutions is now addressed. In Fig. 12, if the sdof solution is followed from $\sigma_2 < 0$ for increasing values, it first crosses $L_1$ at $\sigma_2 = -1.5$, so that a C1 solution is obtained, whose
stability is studied by substituting for Eqs. (33a) and (33b) in the Jacobian matrix $J$. The eigenvalues are found to be solutions of

$$P(k) = \det(J/C_0 k I) = -a_2 a_3^2 \sin \gamma_2 + \lambda \left( -a_2 a_3^2 \sin \gamma_2 - \lambda \right) P_{C2}(\lambda),$$

where $P_{C2}(\lambda)$ governs the eigenvalues of the C1 solution with respect to perturbations contained within the subspace $a_2 = 0$. Hence the perturbations created by the presence of the second configuration are completely described by the first two eigenvalues, which are exactly equal to that obtained when studying the sdof solution (see Eqs. (35d) and (35e)). The C1 solution is thus stable as long as $a_3 \leq L_2(\sigma_2)$ with $a_3$ given now by Eq. (33a). For the C1 solution, $a_3$ (given by Eq. (33a)) takes exactly the value given by the stability condition $L_1$ (Eq. (36)), so that it can be read in Fig. 12 that the C1 solution is stable as long as $L1$ does not cross $L2$. In Fig. 12, the crossing occurs at $\sigma_2 = 0.30$, where a stability exchange is observed: the C1 solution loses its stability in favor of the C2 solution. Thanks to the symmetry of the system, the discussion is equivalent when following the sdof solution for decreasing values from $\sigma_2 > 0$, by replacing C1 by C2.

It has been demonstrated that the discussion on the stability can be made by simply following the values taken by the amplitude $a_3$ of the directly excited axisymmetric mode, and that the coupling occurs either with the first configuration, or with the second. The imperfections of the system avoid simultaneous energy transfer to the two configurations. A stability exchange occurs. Hence travelling waves are not possible.

5.4. Generalized stability curves

Fig. 13 displays the different solutions for a typical case. All branches of solutions are obtained analytically from the results of Sections 5.2 and 5.3 and have been systematically verified by numerical simulations using the software DsTool. When increasing $\sigma_2$, one observes first the sdof solution. At $\sigma_2 = -1.5$, the first coupling occurs, with the first asymmetric configuration: $a_1$ follows the C1 branch, as well as $a_3$. At $\sigma_2 = \sigma_2 = 0.12$, the stability exchange occurs: $a_1$ goes down to zero while $a_2$ grows up to the C2 branch,
and $a_3$ follows the C2 branch until $\sigma_2 = 1.36$. Hysteretic behaviour is present: when decreasing the excitation frequency, the second configuration is excited first for $\sigma_2 = 1.14$, the stability exchange occurs at the same value $\sigma_2 = 0.12$, from which the first configuration is excited until $\sigma_2 = \frac{C_0}{3.2}$.

A complete parametric study of all possible cases is difficult to formulate because of the size of the parameter space. Nonetheless, we will give now briefly a few guidelines of the possible features by changing two important physical parameters: the internal detuning between the two configurations $r_0$ and the amplitude of the forcing $Q$.

The stability analysis have proven that a mere glance at the relative position of the two stability curves $L_1$ and $L_2$ is sufficient to have a comprehensive idea of which coupling will occur. In particular, if e.g. configuration 1 is much more damped than the other, or if the coupling coefficient $x_1$ is small (see Fig. 12), the stability curve $L_1$ is reached for large $Q$ values only, and thus the main observation is related to a coupling with the second configuration.

Fig. 14 shows the different behaviour exhibited when increasing the internal detuning $r_0$, when all other coefficients are related to a perfect case (i.e. $x_1 = x_2, x_3 = x_4, \mu_1 = \mu_2 = \mu_3$). It is assumed in addition that $r_1 = 1$.

When $r_0$ is small (Fig. 14(a)–(b): $r_0 = 0.1$). The second configuration is mainly observed because the $L_2$ curve is under $L_1$ in a wide instability range: $\tilde{\sigma}_2 \leq \sigma_2 \leq 0.26$, where $\tilde{\sigma}_2 = L_1 \cap L_2 = -1.17$ represents the intersection point. An opposite result would have been observed by setting $\sigma_1 = -1$. Increasing $r_0$ leads to move the intersection point $\tilde{\sigma}_2$. At $r_0 = 1.1$ (Fig. 14(c)–(d)), the C2 branch becomes very short, and the coupling mainly occurs with the first configuration. As $L_2$ still crosses the sdof solution around $\sigma_2 = 1.1$, a short C2 branch is observed. In this specific case, an increasing sweep of the excitation frequency will then produce successively: the sdof solution ($\sigma_2 \leq -1.17$), the C1 solution ($-1.17 \leq \sigma_2 \leq 0.11$), the C2 solution ($0.11 \leq \sigma_2 \leq 0.31$), the sdof solution ($0.31 \leq \sigma_2 \leq 0.96$), the C2 solution ($0.96 \leq \sigma_2 \leq 1.40$) and finally the sdof solution. For higher values of $r_0$ (Fig. 14(e)–(f): $r_0 = 1.4$), no stable branches corresponding to C2 are present. Hence the coupling with the second configuration will not occur anymore. However, the effect of the second configuration is still present, unless the limiting value of the C1 branch defined by

![Generalized stability curve for the case: $x_1 = 1, x_2 = 2, x_3 = 3, x_4 = 4, \mu_1 = \mu_3 = 0.1, \mu_2 = 0.2, Q = 16, \omega_1 = 4, \omega_2 = 4.09$, $\omega_3 = 8.1$. Stable branches are plotted with solid lines, all other branches are unstable.](image-url)
\[
\sigma_2^{\text{max}} (\text{C1}) = \left( \frac{Q x_1}{4 \omega_1 \omega_3 - \mu_3 \sigma_1} \right) \left( 2 \mu_3 + \mu_1 \right)
\]  

is lower than \( \sigma_2 \). One can see in Fig. 14(f) that the stable portion of the C1 branch is shortened because of the second configuration. If one increases \( \sigma_0 \) further, the situation where \( \sigma_2 > \sigma_2^{\text{max}} (\text{C1}) \) happens, the stable
portion of the C1 branch is not shortened and all happens as if only the first configuration was present in the dynamics.

The variations of the amplitudes of the solutions can be represented as functions of $Q$ in order to highlight the phenomenon of saturation of the directly excited mode. Eq. (33a,b) and (34a,b) are then plotted for a given $\sigma_2$ and a variable $Q$. The value $\sigma_2 = L_1 \cap L_2$ which determines the stability exchange, is independent of $Q$. Thus for a given external detuning, no stability exchange occurs, so that representation of this curves are the same as the already studied 1:2 resonance (see e.g. Nayfeh and Raouf, 1987; Nayfeh and Mook, 1979; Haddow et al., 1984).

5.5. Solution for the deflection

In steady state, the deflection of the shell is governed by Eq. (24), with the time functions for the three modes defined at first-order by

\[ q_1(t) = a_1 \cos \left( \frac{\Omega}{2} t - \frac{\gamma_1 + \gamma_3}{2} \right), \tag{41a} \]

\[ q_2(t) = a_2 \cos \left( \frac{\Omega}{2} t - \frac{\gamma_2 + \gamma_3}{2} \right), \tag{41b} \]

\[ q_3(t) = a_3 \cos(\Omega t - \gamma_3), \tag{41c} \]

where $a_i$ and $\gamma_i$ take the values of a particular stable fixed point. Thus, $\gamma_3$ is the phase difference between directly excited mode $q_3$ and excitation, and $\gamma_1$ and $\gamma_2$ are the phase differences between modes excited through internal resonance on the one hand—respectively $q_1$ and $q_2$—and $q_3$ on the other hand.

6. Conclusion

In this paper, a detailed analysis of the non-linear vibrations of thin shallow spherical shells with a free edge has been proposed. The validity range of the governing equations has been quantified analytically and by comparison with a numerical solution. Then, a method of resolution via projection onto the linear modes basis has been detailed, hence presenting the general problem including asymmetric vibrations in a uniform manner.

The major set of results is the general non-linear modal interaction rules that have been established, thanks to computation of all coefficients of the non-linear quadratic and cubic terms that appear in the differential equations. Those coefficients are of major interest as their values govern the energy exchanges between mode that are likely to appear at the non-linear stage. It has been shown that an internal resonance relation between the natural frequencies of the shell is not a sufficient condition for the non-linear modal interaction to occur, since some coefficients of the non-linear terms vanish. This is a consequence of the rotational symmetry of the geometry of the structure, and coupling rules that hold on the number of nodal diameters of the involved modes have been derived. It is thus possible to predict if a particular non-linear energy exchange between modes is possible by considering only the linear modal analysis of the structure: the values of the natural frequencies determine the possible internal resonances and the number of nodal diameters of the involved modes enable to conclude on the activation of the modal interaction. Finally, an application has been treated: the specific case of a 1:1:2 internal resonance has been revisited, with emphasis on the effect of the slight imperfections of the structure on the energy transfers.

Beyond the important results derived throughout this study, the developed model framework can now be used for studying the rich variety of behaviour exhibited by non-linear shell vibrations. As the results of this
article are based on the rotational symmetry of the structure, similar results can be expected for other axisymmetric shells (cylindrical, conical or any profile). An experimental validation of the 1:1:2 internal resonance will be soon reported, showing the validity range and the precision of the model. More generally, this study can serve as a basis for analytical, or numerical-analytical solutions, computations of non-linear normal modes for prediction of the trend of non-linearity, or, in a different point of view, for analysis and synthesis of the sound produced by musical instruments such as cymbals and gongs (Chaigne et al., 2004).

Appendix A. Expression of the eigenmodes of the shell

This section is based on the work of Johnson and Reissner (1956), to which the interested reader can refer for further details.

A.1. General case

The eigenmodes are solutions of the linear, undamped and homogeneous problem related to Eqs. (11a) and (11b), that is written

\[ \Delta \Delta w + \varepsilon_4 \Delta F + \ddot{w} = 0, \]  
\[ \Delta \Delta F = \frac{a^4}{Rh^3} \Delta w. \]  

(A.1a)

(A.1b)

The solution is separated in space and time by

\[ w(r, \theta, t) = \Phi(r, \theta)q(t) \quad \text{and} \quad F(r, \theta, t) = \frac{a^4}{Rh^3} \Psi(r, \theta)q(t), \]  

(A.2)

where \( w \) and \( F \) have the same time dependence because \( F \) is slaved to \( w \) by Eq. (A.1b). Thus, \( \Phi \) and \( \Psi \) are solutions of

\[ \Delta \Delta \Phi + \chi \Delta \Psi - \omega^2 \Phi = 0 \quad \text{and} \quad \Delta \Delta \Psi = \Delta \Phi. \]  

(A.3)

Eq. (A.3) writes

\[ \Delta [\Delta \Delta + \chi - \omega^2] \Phi = 0, \]  

(A.4)

where curvature parameter \( \chi \) is defined by Eq. (8a). Two cases must now be considered.

- **Case I: modes written in terms of Bessel functions**

\[ \omega^2 = \chi + \zeta^4, \quad \Delta [\Delta \Delta - \zeta^4] \Phi(r, 0) = 0, \]  

(A.5)

\[ \Phi_{kn}(r, 0) = \kappa_{kn} \left[ A_k(\zeta_{kn})r^k + J_k(\zeta_{kn}r) + C_k(\zeta_{kn})I_k(\zeta_{kn}r) \right] \begin{pmatrix} \cos k\theta \\ \sin k\theta \end{pmatrix}, \]  

(A.6)
\[ \Psi_{kn}(r, \theta) = \kappa_{kn} \left[ D_k(\zeta_{kn})r^k + \left( 1 + \frac{\zeta_{kn}}{\zeta} \right) \frac{A_k(\zeta_{kn})}{4(k+1)} r^{k+2} - \frac{1}{\zeta_{kn}} (J_k(\zeta_{kn}r) - C_k(\zeta_{kn})I_k(\zeta_{kn}r)) \right] \cos k\theta \sin k\theta. \quad (A.7) \]

**Case II: modes written in terms of Kelvin functions**

\[ \zeta < \zeta_{cr}, \quad \omega^2 = \zeta - \zeta^4, \quad \Delta[\Delta + \zeta^4] \Phi(r, \theta) = 0, \quad (A.8) \]

\[ \Phi_{kn}(r, \theta) = \kappa_{kn} \left[ A_k(\zeta_{kn}r) + \frac{\zeta_{kn}}{\zeta_{kn}} \frac{C_k(\zeta_{kn})}{\zeta_{kn}} \right] \frac{\cos k\theta}{\sin k\theta}, \quad (A.9) \]

\[ \Psi_{kn}(r, \theta) = \kappa_{kn} \left[ D_k(\zeta_{kn})r^k + \left( 1 + \frac{\zeta_{kn}}{\zeta} \right) \frac{A_k(\zeta_{kn})}{4(k+1)} r^{k+2} + \frac{1}{\zeta_{kn}} (\text{ber}_k(\zeta_{kn}r) - C_k(\zeta_{kn})\text{bei}_k(\zeta_{kn}r)) \right] \cos k\theta \sin k\theta. \quad (A.10) \]

In the above equations, \( A_k, C_k, D_k \) and \( D_k \) are constants depending on boundary conditions, \( \kappa_{kn} \) is a normalization constant, \( k \) is the number of nodal diameters and \( n \) the number of nodal circles. \( J_k \) denotes the Bessel function of the first kind of order \( k \) and \( I_k(x) = J_k(ix) \) with \( i = \sqrt{-1} \). Kelvin functions are defined by \( \text{ber}_k(x) + i\text{bei}_k(x) = J_k(i^{3/2}x) = (-1)^k I_k(i^{1/2}x) \). The normalization constant \( \kappa_{kn} \) is chosen so that Eq. (22) is fulfilled. Modes \( \Psi_{kn} \) are not normalized (\( \kappa_{kn} \) appears in \( \Phi_{kn} \) as well as in \( \Psi_{kn} \)) as they are slaved to transverse modes \( \Phi_{kn} \).

**A.2. Free-edge boundary conditions**

Values of \( \zeta, A_k, C_k \) and \( D_k \) are determined by introducing the boundary conditions. In the case of a free-edge, one obtains in a dimensionless form (see Eqs. (5a)–(5d)):

\[ \Phi \text{ and } \Psi \text{ are bounded at } r = 0, \quad (A.11a) \]

\[ \Phi_{rr} + v\Phi_r + v\Phi_{\theta\theta} = 0 \quad \text{at } r = 1, \quad (A.11b) \]

\[ \Phi_{r\theta} + \Phi_{\theta r} - \Phi_r + (2 - v)\Phi_{r\theta} - (3 - v)\Phi_{\theta\theta} = 0 \quad \text{at } r = 1, \quad (A.11c) \]

\[ \Psi_r + \Psi_{\theta\theta} = 0, \quad \Psi_{r\theta} - \Psi_{\theta r} = 0 \quad \text{at } r = 1. \quad (A.11d) \]

The expressions of the modes in terms of Bessel functions or Kelvin functions depends on the values of \( k, n \) and \( \chi \), results that are summarized in Table A.3.

**• Axisymmetric modes and modes with one nodal diameter \((k \in \{0, 1\})**

The modes express in terms of Bessel functions, so that \( \zeta_{kn} = \zeta_{kn}^{(0)} \) is the \( n \)th zero of the equation

\[ \mathcal{D}_k(\zeta) = 0 \quad (A.12) \]

with \( \mathcal{D}_k \) defined in Table A.1. This equation is independent of \( \chi \)—and then of curvature—and is the equation with whom are calculated the natural frequencies (denoted by \( \omega_{kn}^{(0)} = \omega_{kn}^{(0)2} \)) of the circular plate obtained with \( \chi = 0 \). The natural frequencies of the shell are then, from Eq. (A.5), for all \( k \in \{0, 1\} \) and for all \( n \)

\[ \omega_{kn} = \sqrt{\chi + \zeta_{kn}^4} = \sqrt{\chi + \omega_{kn}^{(0)2}}. \quad (A.13) \]
The mode shapes are obtained by Eqs. (A.6), (A.7) and coefficients of Table A.1. One can show that \( A_0 = A_1 = 0 \). As a consequence, for all \( k \in \{0, 1\} \), both transverse and membrane mode shapes do not depend on curvature and transverse modes \( \Phi_{kn} \) are identical to those of the corresponding plate (see e.g. Touzé et al., 2002). Thus, for all \( k \in \{0, 1\} \) and for all \( n 
\)

\[
\Phi_{kn}(r, \theta) = \kappa_{kn} \left( J_k(\zeta_{kn}) - \tilde{J}_k(\zeta_{kn}) \right) \sin k\theta
\]

with \( \tilde{J}_k(\zeta) \) and \( \tilde{I}_k(\zeta) \) defined in Table A.1.

- **Asymmetric modes with** \( k \geq 2 \)

  The particular value of \( \chi \) defined by

  \[
  \chi^4_k = \frac{(1 - v)(3 + v)k^2(k^2 - 1)}{1 + \frac{1}{4}(1 - v)(k - 2) - \frac{k(k^2 + 1)v(1 - v)}{16(k + 2)(k + 3)}}
  \]

  determines whether the modes write in terms of Kelvin functions or Bessel functions.

  - If \( \chi < \chi^4_k \), all modes are written in terms of Bessel functions. \( \zeta_{kn} \) is the \((n + 1)\)th zero of the equation

    \[
    \frac{\zeta^4}{\chi} = \frac{\mathcal{S}_k(\zeta)}{\mathcal{R}_k(\zeta)} - 1 \quad \text{and} \quad \omega_{kn} = \sqrt{\chi + \zeta^4_{kn}}.
    \]

  In the above equations,

  \[
  \mathcal{S}_k(\zeta) = \frac{k}{\zeta}(v - 1)(k - 1) \left[ J_k(\zeta) \left( \frac{k}{\zeta} I_k(\zeta) - J_k(\zeta) \right) + \tilde{I}_k(\zeta) \left( \frac{k}{\zeta} J_k(\zeta) - J_k(\zeta) \right) \right],
  \]

  \[
  \mathcal{R}_k(\zeta) = -\frac{1}{2(1 + k)} \mathcal{D}_k(\zeta),
  \]

  with \( \tilde{J}_k(\zeta) \), \( \tilde{I}_k(\zeta) \) and \( \mathcal{D}_k(\zeta) \) defined in Table A.1. The mode shapes are obtained by Eqs. (A.6) and (A.7) and coefficients of Table A.1.

  - If \( \chi > \chi^4_k \), modes with no nodal circles (\( n = 0 \)) write in terms of Kelvin functions and the others in terms of Bessel functions. Thus, \( \zeta_{k0} \) is the only zero of equation:

    \[
    \frac{\zeta^4}{\chi} = 1 - \frac{\mathcal{U}_k(\zeta)}{\mathcal{F}_k(\zeta)} \quad \text{and} \quad \omega_{k0} = \sqrt{\chi - \zeta^4_{k0}}.
    \]
Appendix B. Expression of functions

</tr>
</tbody>
</table>

$D_k(\zeta) = M_{33}M_{43} - M_{34}M_{44}$

$\tilde{J}_k(\zeta) = k M_{33} + M_{43}$, $\tilde{I}_k(\zeta) = k M_{34} + M_{44}$

$C_k(\zeta) = -\frac{A_k(\zeta)}{M_{34}}$

$A_k(\zeta) = \frac{2 (\xi k^2 + f k^4 - 2 (\xi k^2 - 1))}{\xi}$

$D_k(\zeta) = -\frac{1}{k} [C_k(\zeta) (k + 2) \text{ber}_1(\zeta) - (3 \text{ber}_1(\zeta) + (k + 2) \text{beir}_1(\zeta) - \text{beir}_1(\zeta))]$

Table A.3

Summary of calculation of modes of a spherical shell

$k \in \{0, 1\}$

| $\forall n \geq 1$ | “Bessel”
|----------------|-------------------------|
| $\omega_{kn} = \sqrt{\chi + \omega_{kn}^{(0)}^2}$
| Eqs. (A.7), (A.12) and (A.14), Table A.1
| $k \geq 2$ | $n = 0$
| $\chi < \chi_k^{(\text{lim})}$ | “Bessel”
| $\omega_{kn} = \sqrt{\chi + \xi_k^{(0)}}$
| Eqs. (A.6), (A.7) and (A.16), Table A.1
| $k \geq 2$ | $n \geq 1$
| $\chi > \chi_k^{(\text{lim})}$ | “Bessel”
| $\omega_{kn} = \sqrt{\chi + \xi_k^{(0)}}$
| Eqs. (A.6), (A.7) and (A.16), Table A.1

$\omega_{kn}^{(0)}$ are the frequencies of the corresponding circular plate and $\chi_k^{(\text{lim})}$ is defined by Eq. (A.15).

In the above equation

$$\mathcal{U}_k(\zeta) = -\frac{k}{\zeta} (v - 1) (k - 1) \left[ \tilde{J}_k(\zeta) \left( \frac{k}{\zeta} \text{ber}_k(\zeta) - \text{ber}_k'(\zeta) \right) + \tilde{I}_k(\zeta) \left( \frac{k}{\zeta} \text{beir}_k(\zeta) - \text{beir}_k'(\zeta) \right) \right]$$

(A.20)

$$\mathcal{F}_k(\zeta) = -\frac{1}{2(1 + k)} \mathcal{D}_k(\zeta)$$

(A.21)

and $\tilde{J}_k(\zeta)$, $\tilde{I}_k(\zeta)$ and $\mathcal{D}_k(\zeta)$ are defined in Table A.2. The corresponding mode shapes are obtained by Eq. (A.9) and (A.10) and coefficients of Table A.2. For modes with at least one nodal circle ($n \geq 1$), $\zeta_{kn}$ is the $n$th zero of Eq. (A.16), $\omega_{kn}$ is defined by Eq. (A.16) and the corresponding mode shapes writes with Eqs. (A.6) and (A.7) and coefficients of Table A.1.

Appendix B. Expression of functions $\Upsilon_b$

Functions $\Upsilon_b(r, \theta)$ are solutions of

$$(\Delta - \zeta^4) \Upsilon = 0,$$  \hspace{1cm} (B.1a)
One obtains

\begin{equation}
\mathcal{Y}_{lm}(r, \theta) = \zeta_{lm} \left[ J_l(\zeta_{lm} r) - \frac{J_1(\zeta_{lm})}{I_1(\zeta_{lm})} I_1(\zeta_{lm} r) \right] \cos l \theta \sin l \theta \tag{B.2}
\end{equation}

where the \( \zeta_{lm} \) is the \( n \)th solution of the following equation:

\begin{equation}
J_{l-1}(\zeta) I_l(\zeta) - I_{l-1}(\zeta) J_l(\zeta) = 0. \tag{B.3}
\end{equation}

Computed values of the \( \zeta_{lm} \) can be found in Leissa (1993a). The normalization constant \( \lambda_{lm} \) is chosen so that Eq. (17) is fulfilled.

### Appendix C. Calculation of coupling coefficients \( \beta_{pq}^\gamma \) and \( \gamma_{ppq}^\delta \)

The different modes that are necessary for the calculation of coefficients \( \beta_{pq}^\gamma \) and \( \gamma_{ppq}^\delta \) (Eqs. (20) and (21)) are noted separated in \( r \) and \( \theta \):

\[ \Phi_{00}(r) = R_{00}(r) \; \text{for} \; k = 0; \quad \Phi_{k00}(r, \theta) = R_{k0}(r) \begin{cases} \cos k \theta & \text{for} \; k = 0; \\ \sin k \theta & \text{for} \; k \geq 1; \end{cases} \]

\[ \Psi_{00}(r) = S_{00}(r) \; \text{for} \; k = 0; \quad \Psi_{k00}(r, \theta) = S_{k0}(r) \begin{cases} \cos k \theta & \text{for} \; k = 0; \\ \sin k \theta & \text{for} \; k \geq 1; \end{cases} \]

\[ T_{00}(r) = T_{00}(r) \; \text{for} \; l = 0; \quad T_{lm0}(r, \theta) = T_{lm}(r) \begin{cases} \cos l \theta & \text{for} \; l = 0; \\ \sin l \theta & \text{for} \; l \geq 1. \end{cases} \]

In the following, subscripts \( \gamma \) and \( \delta \) will denote the nature in cosine (\( \gamma = 1 \)) or sine (\( \gamma = 2 \)) of the considered mode. In order to lighten notations, subscripts \( p, q, s \) and \( b \) will sometimes replace triplets \( (k_p, n_p, \gamma_p) \) to identify modes \( \Phi, \Psi \) and \( \mathcal{Y} \). For example, \( \Phi_p \) is the same than \( \Phi_{k_p, n_p, \gamma_p} \), so that \( \Phi_p(r, \theta) = R_{k_p, n_p}(r) \cos k_p \theta \) if \( \gamma_p = 1 \) and \( \Phi_p(r, \theta) = R_{k_p, n_p}(r) \sin k_p \theta \) if \( \gamma_p = 2 \). In the same manner, \( R_p(r) = R_{k_p, n_p}(r) \).

#### C.1. Quadratic coefficients \( \beta_{pq}^\gamma \)

Their expression is (Eq. (20)):

\begin{equation}
\beta_{pq}^\gamma = \iint_{\mathcal{S}_\perp} \Phi_s L(\Phi_p, \Psi_q) dS - \frac{1}{2} \sum_{b=1}^{\infty} \left( \int_{\mathcal{S}_\perp} L(\Phi_p, \Phi_q) \mathcal{Y}_b dS \right) \left( \int_{\mathcal{S}_\perp} \Phi_s \mathcal{Y}_b dS \right) \tag{C.1}
\end{equation}

Following the definition of \( L \) (Eq. (4)) and integrating over domain \( \mathcal{S}_\perp \) by separation of variables \( r \) and \( \theta \), one obtains

\begin{equation}
\mathcal{J}(p, q, b) = I_1(p, q, b) \Pi_{\gamma_p, q}^{(1)}(k_p, k_q, l) - 2k_pk_qI_2(p, q, b) \Pi_{\gamma_p, q}^{(2)}(k_p, k_q, l), \tag{C.2}
\end{equation}
\[ \mathcal{J}_p^p(s, p, q) = J_1^{\gamma}(s, p, q) I^{(1)}_{\gamma \gamma q / \gamma q} (k_x, k_p, k_q) - 2k_p k_q J_2^{\gamma}(s, p, q) I^{(3)}_{\gamma \gamma q / \gamma q} (k_x, k_p, k_q), \]
\[ \mathcal{K}(s, b) = K(s, b) I^{(4)}_{\gamma \gamma q / \gamma q} (s, b), \]

where

\[ I_1(p, q, b) = \int_0^1 \left[ R_p' \left( R_q' - k_p^2 \frac{R_p}{r} \right) + R_q' \left( R_p' - k_q^2 \frac{R_q}{r} \right) \right] T_b \, dr, \]
\[ I_2(p, q, b) = \int_0^1 \frac{1}{r} \left[ R_p' - \frac{R_p}{r} \right] \left[ R_q' - \frac{R_q}{r} \right] T_b \, dr, \]
\[ J_1^p(s, p, q) = \int_0^1 R_s \left[ R_p' \left( S_q' - k_s^2 \frac{S_q}{r} \right) + S_q' \left( R_p' - k_q^2 \frac{R_p}{r} \right) \right] \, dr, \]
\[ J_2^p(s, p, q) = \int_0^1 R_s \frac{1}{r} \left[ R_p' - \frac{R_p}{r} \right] \left[ S_q' - \frac{S_q}{r} \right] \, dr, \]
\[ K(s, b) = \int_0^1 R_s \left( r T_b' + T_b - \frac{l^2}{r} T_b \right) \, dr \]

and

\[ I^{(1)}_{\gamma \gamma q / \gamma q} (k_x, k_p, k_q) = \int_0^{2\pi} \begin{vmatrix} \cos k \theta & \cos k' \theta & \cos l \theta \\ \sin k \theta & \sin k' \theta & \sin l \theta \end{vmatrix} \, d\theta, \]
\[ I^{(2)}_{\gamma \gamma q / \gamma q} (k_x, k_p, k_q) = \int_0^{2\pi} \begin{vmatrix} - \sin k \theta & - \sin k' \theta & \cos l \theta \\ \cos k \theta & \cos k' \theta & \sin l \theta \end{vmatrix} \, d\theta, \]
\[ I^{(3)}_{\gamma \gamma q / \gamma q} (k_x, k_p, k_q) = \int_0^{2\pi} \begin{vmatrix} \cos k \theta & - \sin k' \theta & - \sin l \theta \\ \sin k \theta & \cos k' \theta & \cos l \theta \end{vmatrix} \, d\theta, \]
\[ I^{(4)}_{\gamma \gamma q / \gamma q} (k_x, k_p, k_q) = \int_0^{2\pi} \begin{vmatrix} \cos k \theta & \cos l \theta \\ \sin k \theta & \sin l \theta \end{vmatrix} \, d\theta. \]

The above notations mean that any \( I^{(\gamma, \gamma', \delta)}_{\gamma \gamma q / \gamma q} \) is obtained by making the product of three functions sine and/or cosine, each one being taken in a column of the above matrices. \((\gamma, \gamma', \delta)\) refers, respectively, to the first, the second and the third column and their values determine the line. For example, with \((\gamma, \gamma', \delta) = (2, 1, 2)\)

\[ I^{(3)}_{\gamma \gamma q / \gamma q} (k_x, k_p, k_q) = -\int_0^{2\pi} \sin k \theta \sin k' \theta \cos l \theta \, d\theta. \]

Several coefficients \( I \) equal zero for specific values of \((k, k', l)\) (the numbers of nodal diameters) and \((\gamma, \gamma', \delta)\) (the nature in sine and/or cosine). This is the cause of the vanishing of some coefficients \( \beta_{pq} \). The results on
Table C.1

$J(p, q, b)$, $\mathcal{K}(s, b)$ and $J^T(s, p, q)$ are summarized in Table C.1. To obtain a non-zero $J^T_{pq}$, one must have either $J^T(s, p, q) \neq 0$ or at least one mode $T_b$ so that $J(p, q, b) \mathcal{K}(s, b) \neq 0$. It is summarized in Table 2.

C.2. Cubic coefficients $I^s_{pq}$

Their expression is (Eq. (20)):

$$I^s_{pq} = \frac{1}{2} \sum_{b=1}^{+\infty} \frac{1}{\xi_b} \int_{\mathcal{J}(p, q, b)} \Phi_u L(\Phi_u, \Phi_v) \gamma_b d\mathcal{S} \int_{\mathcal{J}^T(s, u, b)} \Phi_u L(\Phi_u, \Upsilon_b) d\mathcal{S},$$

where $\mathcal{J}(p, q, b)$ has been calculated in the above section and $\mathcal{J}^T(s, u, b)$ has the same structure than $\mathcal{J}^T(s, p, q)$ and writes

$$J^T(s, u, b) = J^T_1(s, u, b) \Pi^{(1)}_{\gamma, \gamma, \delta}(k_s, k_u, l) - 2k_u l J^T_2(s, u, b) \Pi^{(3)}_{\gamma, \gamma, \delta}(k_s, k_u, l),$$

where

$$J^T_1(s, u, b) = \int_0^1 R_u \left[ R_u \left( T_b' - \frac{l^2 T_b}{r} \right) + T_b' \left( R_u' - \frac{k_u^2 R_u}{r} \right) \right] dr,$$

$$J^T_2(s, u, b) = \int_0^1 R_u \left[ R_u' \left( T_b' - \frac{k_u^2 R_u}{r} \right) \right] \left[ T_b' - \frac{T_b}{r} \right] dr.$$

Again, non-zero $I^s_{pq}$ are obtained if $J(p, q, b) J^T(s, u, b) \neq 0$, cases specified in Table C.2. The consequences on $I^s_{pq}$ are summarized in Table 2.
